## 1st Draft Valencia Island GWB Description September 2005

## Valencia Island GWB: Summary of Initial Characterisation.

	rometric Area cal Authority	Associated surface water features	Associated terrestrial ecosystem(s)	Area (km²)	
	22 Kerry Co Co	No lakes Several unnamed streams.	No groundwater dependent terrestrial ecosystems (O'Riain, 2004).	~26	
Topograph y	700 (Census 2002 southwestern tip o of the northern ed	Valencia Island is located just off the west Kerry coastline, approximately 500m off the mainland, with a population of approximately 700 (Census 2002). Elevations range from 0-260mAOD, with the highest mountainous ground in the northern end of the island. The southwestern tip of the island is also rugged and steep. The island is bordered by a rocky coastline, which is comprises cliffs along much of the northern edge of the island. Figure 1 shows the location and boundaries of the GWB. Cahersiveen GWB is nearest GWB. There are several small streams.			
Geology and Aquifers	Aquifer categories	The main aquifer category is:  Pl: Poor aquifer, generally unproductive except for local zones.			
	Main aquifer lithologies	Devonian Old Red Sandstones			
	Key structures	The widespread faulting and folding associated with the Variscan Orogeny in the south of Ireland has given rise to zones of enhanced permeability in the mudstones and sandstones. These can occur in the immediate vicinity of faults and near the axes of folds. The mainly fine-grained nature of the rocks however means that such zones are generally local.			
	Key properties	[TAKEN FROM CAHERSIVEEN GWB] Permeability generally decreases rapidly with depth in all aquifers in this GWB. In general, the ORS aquifer transmissivities will range 2-20 m²/d, with median values occurring towards the lower end of the range. However, 'Excellent' yielding wells (>400 m³/d) are known in some of the ORS units in other locations – these yields are usually associated with boreholes being situated on fault zones. Summer yields are sometimes unsustainable. Transmissivities in the small occurrences of other rock types in this GWB will be similarly low. Aquifer storativity will be low in all rock units. Groundwater gradients are likely to be in the range 0.01 to 0.04.			
	Thickness	The Devonian ORS can be up to several kilometres thick in this region (Pracht 1996). However, in all aquifers within this GWB, most groundwater flow occurs within the top 15-20 m of the aquifer, in the layer that comprises a weathered zone of a few metres and a connected fractured zone below this. Deeper flows occur along generally isolated faults or significant fractures.			
ata	Lithologies	Devonian Sandstone Till (TDSs) is present on the southern half of the island whilst the northern half of the island is predominantly rock close.			
Overlying Strata	Thickness	Subsoil is generally less than 3 m thick but up to 10m thick subsoil is present in places.			
	% area aquifer near surface	[Further Information to be added at a later date]			
	Vulnerability	[Further Information to be added at a later date]			
Rechar ge	Main recharge mechanisms	Diffuse recharge is expected to occur via rainfall	l percolating through the subsoil and rock outcrops.		
	Est. recharge rates	[Information to be added to and checked]			
Discharge	Large springs and large known abstractions (m³/d)	No data			
	Main discharge mechanisms	Shallow groundwater is likely to discharge mainly to the small lakes, streams or to seeps along the coastline, but the limited bedrock transmissivity means that the baseflow component of the total streamflow will be low.			
	Hydrochemical Signature	Sandstone rocks ranges from moderately soft to approximately 150-450 µS/cm. High iron (Fe) a of Fe and Mn from the sandstone/shale where re-		ranging ssolution	
Groundwater Flow Paths		Groundwater flow is expected to be concentrated in fractured and weathered zones and in the vicinity of fault zones. Flow paths are likely to be short (30-300 m) with groundwater discharging rapidly to the lakes, streams or to seeps along the coastline. Groundwater flow directions are expected to follow topography.			
Groundwater & Surface water interactions		Groundwater will discharge locally to the small lakes, small springs and seeps. Owing to the poor productivity of the aquifers in this body it is unlikely that any major groundwater - surface water interactions occur. Baseflow is likely to be relatively low.			

Conceptual model	•	<ul> <li>Groundwater flow is expected to be concentrated in fractured and weathered zones and in the vicinity of fault zones.</li> <li>Diffuse recharge is expected to occur via rainfall percolating through the subsoil and rock outcrops.</li> <li>Flow paths are likely to be short (30-300 m) with groundwater discharging rapidly to the lakes, streams or to seeps along the coastline.</li> <li>Flow directions are expected to follow topography.</li> </ul>
